5 Correlations between the sample means difference and standardizers of all estimators, and  
 6 implications on biases and variances of all estimators

7 **Introduction**

8 The  $d$ -family effect sizes are commonly used with “between-subject” designs where  
 9 individuals are randomly assigned into one of two independent groups and groups scores  
 10 means are compared. The population effect size is defined as

$$\delta = \frac{\mu_1 - \mu_2}{\sigma} \quad (1)$$

11 where both populations follow a normal distribution with mean  $\mu_j$  in the  $j^{th}$   
 12 population ( $j=1,2$ ) and common standard deviation  $\sigma$ . They exist different estimators of this  
 13 population effect size, varying as a function of the chosen standardizer ( $\sigma$ ). When the  
 14 equality of variances assumption is met,  $\sigma$  is estimated by pooling both samples standard  
 15 deviations ( $S_1$  and  $S_2$ ):

$$\sigma_{Cohen's\ d_s} = \sqrt{\frac{(n_1 - 1) \times S_1^2 + (n_2 - 1) \times S_2^2}{n_1 + n_2 - 2}} \quad (2)$$

16 When the equality of variances assumption is not met, we are considering three  
 17 alternative estimates:

- 18 • Using the standard deviation of the control group ( $S_c$ ) as standardizer:

$$S_{Glass's\ d_s} = S_c \quad (3)$$

- 19 • Using a standardizer that takes the sample sizes allocation ratio  $(\frac{n_1}{n_2})$  into account:

$$S_{Shieh's\ d_s} = \sqrt{S_1^2/q_1 + S_2^2/q_2}; \quad q_j = \frac{n_j}{N} (j = 1, 2) \quad (4)$$

- 20 • Or using the square root of the non pooled average of both variance estimates ( $S_1^2$  and  
 21  $S_2^2$ ) as standardizer:

$$S_{Cohen's\ d'_s} = \sqrt{\frac{(S_1^2 + S_2^2)}{2}} \quad (5)$$

22 As we previously mentioned, using these formulas implies meeting the assumption of  
 23 normality. Using them when distributions are not normal will have consequences on both  
 24 bias and variance of all estimators. More specifically, when samples are extracted from  
 25 skewed distribution, correlations might occur between the sample means difference ( $\bar{X}_1 - \bar{X}_2$ )  
 26 and standardizers ( $\sigma$ ). Studying when these correlations occur is the main goal of this  
 27 appendix. To this end, we will distinguish 4 situations, as a function of the sample sizes ratio  
 28 ( $\frac{n_1}{n_2} = 1$  vs.  $\frac{n_1}{n_2} \neq 1$ ) and the population SD-ratio ( $\frac{\sigma_1}{\sigma_2} = 1$  vs.  $\frac{\sigma_1}{\sigma_2} \neq 1$ ), but before that, we  
 29 will briefly introduce the impact of correlations on the bias.

30 Note that we will compute correlations using the coefficient of Spearman's  $\rho$ . We  
 31 decided to use Spearman's  $\rho$  instead of Pearson's  $\rho$  because some plots revealed non-perfectly  
 32 linear relations.

33 **How correlations between the mean difference ( $\bar{X}_1 - \bar{X}_2$ ) and standardizers  
 34 affect the bias of estimators.**

35 When distributions are right-skewed, there is a positive (negative) correlation between  
 36  $S_1$  ( $S_2$ ) and ( $\bar{X}_1 - \bar{X}_2$ ). When distributions are left-skewed, there is a negative (positive)  
 37 correlation between  $S_1$  ( $S_2$ ) and  $\bar{X}_1 - \bar{X}_2$ . When the population mean difference  $\mu_1 - \mu_2$  is  
 38 positive (like in our simulations), an estimator is always less biased and variable when  
 39 choosing a standardizer that is positively correlated with  $\bar{X}_1 - \bar{X}_2$  than when choosing an

<sup>40</sup> estimator that is negatively correlated with  $\bar{X}_1 - \bar{X}_2$ . When the population mean difference  
<sup>41</sup> is negative, the reverse is true.

<sup>42</sup> Faire petits plots pour expliquer cela.

<sup>43</sup> **Correlations between the mean difference ( $\bar{X}_1 - \bar{X}_2$ ) and all standardizers**

<sup>44</sup> **When equal population variances are estimated based on equal sample sizes**  
<sup>45</sup> **(condition a)**

<sup>46</sup> While  $\bar{X}_j$  and  $S_j$  ( $j=1,2$ ) are uncorrelated when samples are extracted from symmetric  
<sup>47</sup> distributions (see Figure 1), there is a non-null correlation between  $\bar{X}_j$  and  $S_j$  when  
<sup>48</sup> distributions are skewed (Zhang, 2007).

<sup>49</sup> More specifically, when distributions are right-skewed, there is a **positive** correlation  
<sup>50</sup> between  $\bar{X}_j$  and  $S_j$  (see the two top plots in Figure 2), resulting in a *positive* correlation  
<sup>51</sup> between  $S_1$  and  $\bar{X}_1 - \bar{X}_2$  and in a *negative* correlation between  $S_2$  and  $\bar{X}_1 - \bar{X}_2$  (see the two  
<sup>52</sup> bottom plots in Figure 2). This can be explained by the fact that  $\bar{X}_1$  and  $\bar{X}_1 - \bar{X}_2$  are  
<sup>53</sup> positively correlated while  $\bar{X}_2$  and  $\bar{X}_1 - \bar{X}_2$  are negatively correlated (of course, correlations  
<sup>54</sup> would be trivially reversed if we computed  $\bar{X}_2 - \bar{X}_1$  instead of  $\bar{X}_1 - \bar{X}_2$ ).

<sup>55</sup> One should also notice that both correlations between  $S_j$  and  $\bar{X}_1 - \bar{X}_2$  are equal, in  
<sup>56</sup> absolute terms (possible tiny differences might be observed due to sampling error in our  
<sup>57</sup> simulations). As a consequence, when computing a standardizer taking both  $S_1$  and  $S_2$  into  
<sup>58</sup> account, it results in a standardizer that is uncorrelated with  $\bar{X}_1 - \bar{X}_2$  (see Figure 3).

<sup>59</sup> On the other hand, when distributions are left-skewed, there is a **negative** correlation  
<sup>60</sup> between  $\bar{X}_j$  and  $S_j$  (see the two top plots in Figure 4), resulting in a *negative* correlation  
<sup>61</sup> between  $S_1$  and  $\bar{X}_1 - \bar{X}_2$  and in a *positive* correlation between  $S_2$  and  $\bar{X}_1 - \bar{X}_2$  (see the two  
<sup>62</sup> bottom plots in Figure 4).

<sup>63</sup> Again, because correlations between  $S_j$  and  $\bar{X}_1 - \bar{X}_2$  are similar in absolute terms, any

<sup>64</sup> standardizers taking both  $S_1$  and  $S_2$  into account will be uncorrelated with  $\bar{X}_1 - \bar{X}_2$  (see  
<sup>65</sup> Figure 5).

<sup>66</sup> **When equal population variances are estimated based on unequal sample sizes**  
<sup>67</sup> **(condition b)**

<sup>68</sup> When distributions are skewed, there are again non-null correlations between  $\bar{X}_j$  and  
<sup>69</sup>  $S_j$ , however  $\text{cor}(S_1, \bar{X}_1) \neq \text{cor}(S_2, \bar{X}_2)$ , because of the different sample sizes.

<sup>70</sup> When distributions are skewed, one observes that the larger the sample size, the lower  
<sup>71</sup> the correlation between  $S_j$  and  $\bar{X}_j$  (See Figures 6 and 7).

<sup>72</sup> This might explain why the magnitude of the correlation between  $S_j$  and  $\bar{X}_1 - \bar{X}_2$  is  
<sup>73</sup> lower in the larger sample (See bottom plots in Figures 8 and 9; note that with no surprise,  
<sup>74</sup> there is a positive (negative) correlation between  $S_1$  and  $\bar{X}_1 - \bar{X}_2$  and a negative (positive)  
<sup>75</sup> correlation between  $S_2$  and  $\bar{X}_1 - \bar{X}_2$  when distribution are right-skewed (left-skewed), as  
<sup>76</sup> illustrated in the two bottom plots of Figures 8 and 9).

<sup>77</sup> This might also explain why the standardizers of Shieh's  $d_s$  and Cohen's  $d'_s$  are this  
<sup>78</sup> time **correlated** with  $\bar{X}_1 - \bar{X}_2$  (see Figures 10 and 11):

<sup>79</sup> - When computing  $S_{\text{Cohen}'s\ d'_s}$ , the same weight is given to both  $S_1$  and  $S_2$ . Therefore,  
<sup>80</sup> it doesn't seem surprising that the sign of the correlation between  $S_{\text{Cohen}'s\ d'_s}$  and  $\bar{X}_1 - \bar{X}_2$  is  
<sup>81</sup> the same as the size of the correlation between  $\bar{X}_1 - \bar{X}_2$  and the  $SD$  of the smallest sample.

<sup>82</sup> - When computing  $S_{\text{Shieh}'s\ d_s}$ , more weight is given to the  $SD$  of the smallest sample, it  
<sup>83</sup> is therefore not really surprising to observe that the correlation between  $S_{\text{Shieh}'s\ d_s}$  and  
<sup>84</sup>  $\bar{X}_1 - \bar{X}_2$  is closer of the correlation between  $S_1$  and  $\bar{X}_1 - \bar{X}_2$   
<sup>85</sup> (i.e.  $\text{cor}(S_{\text{Shieh}'s\ d_s}, \bar{X}_1 - \bar{X}_2) > \text{cor}(S_{\text{Cohen}'s\ d'_s}, \bar{X}_1 - \bar{X}_2)$ )

<sup>86</sup> - When computing  $S_{\text{Cohen}}$ , more weight is given to the  $SD$  of the largest sample, which  
<sup>87</sup> by compensation effect, brings the correlation very close to 0.

88 **When unequal population variances are estimated based on equal sample sizes**  
 89 **(condition c)**

90        When distributions are skewed, there are again non-null correlations between  $\bar{X}_j$  and  
 91  $S_j$ . As illustrated in Figures 12 and 13, the correlation remain the same for any population  
 92  $SD(\sigma)$ .

93        However, the magnitude of the correlation between  $S_j$  and  $\bar{X}_1 - \bar{X}_2$  differ: it is  
 94 stronger in the sample extracted from the larger population variance.

95        This also explain that when computing a standardizer taking both  $S_1$  and  $S_2$  into  
 96 account, it results in a standardizer that is correlated with  $\bar{X}_1 - \bar{X}_2$  (see Figures 16 and 17).  
 97 The correlation between the mean difference ( $\bar{X}_1 - \bar{X}_2$ ) and respectively the standardizer of  
 98 Shieh's  $d_s$ , Cohen's  $d'_s$  and Cohen's  $d_s$  will have the same sign as the correlation between  
 99 ( $\bar{X}_1 - \bar{X}_2$ ) and the larger  $SD$ . Table 1 summarizes the sign of the correlation between  
 100  $\bar{X}_1 - \bar{X}_2$  and respectively  $SD_1$ ,  $SD_2$  and the three standardizers taking both  $SD_1$  and  $SD_2$   
 101 into account (see "Others" in the Table).

102 **When unequal population variances are estimated based on unequal sample  
 103 sizes (conditions d and e)**

Table 1

*Correlation between standardizers ( $SD_1, SD_2$  and others) and  $\bar{X}_1 - \bar{X}_2$ , when samples are extracted from skewed distributions with unequal variances and equal sample sizes, as a function of the SD-ratio.*

| <b>population distribution</b> |   |   |
|--------------------------------|---|---|
|                                | <i>right-skewed</i>   | <i>left-skewed</i>  |
| When $\sigma_1 = \sigma_2$     | $SD_1$ : <i>positive</i><br>$SD_2$ : <i>negative</i><br>Others: <i>null</i>     | $SD_1$ : <i>negative</i><br>$SD_2$ : <i>positive</i><br>Others: <i>null</i>     |
| When $\sigma_1 > \sigma_2$     | $SD_1$ : <i>positive</i><br>$SD_2$ : <i>negative</i><br>Others: <i>positive</i> | $SD_1$ : <i>negative</i><br>$SD_2$ : <i>positive</i><br>Others: <i>negative</i> |
| When $\sigma_1 < \sigma_2$     | $SD_1$ : <i>positive</i><br>$SD_2$ : <i>negative</i><br>Others: <i>negative</i> | $SD_1$ : <i>negative</i><br>$SD_2$ : <i>positive</i><br>Others: <i>positive</i> |

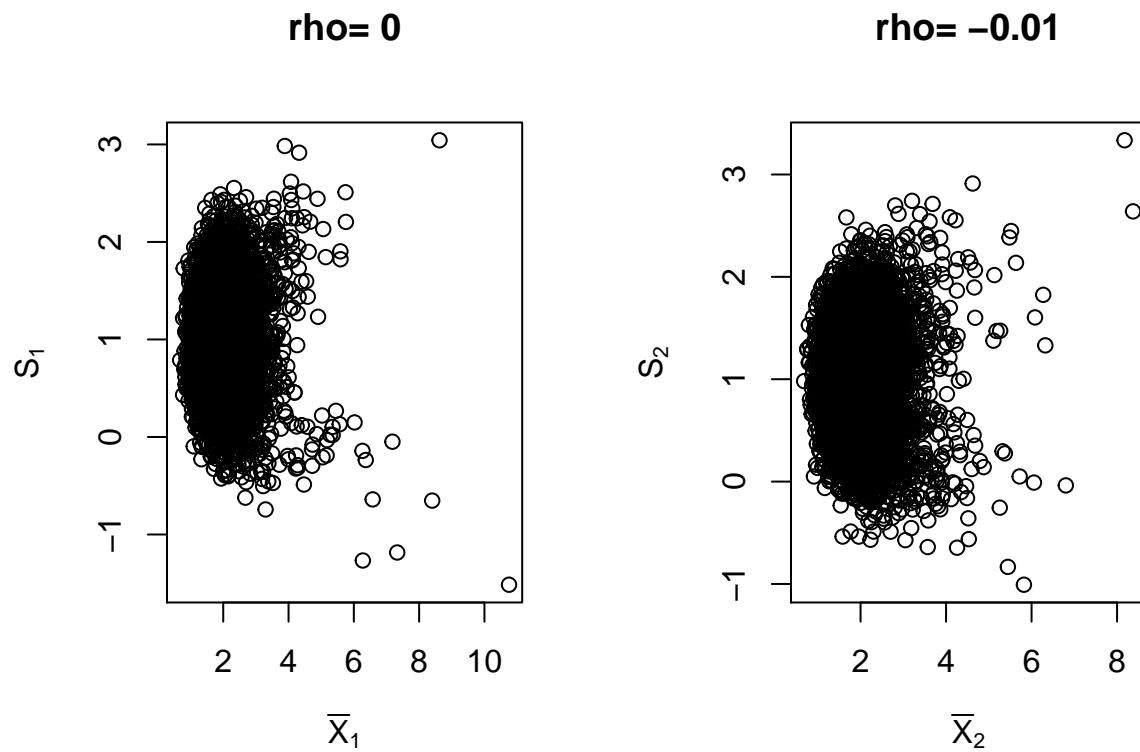

Figure 1.  $S_j$  as a function of  $\bar{X}_j$  ( $j=1,2$ ), when samples are extracted from symmetric distributions ( $\gamma_1 = 0$ )

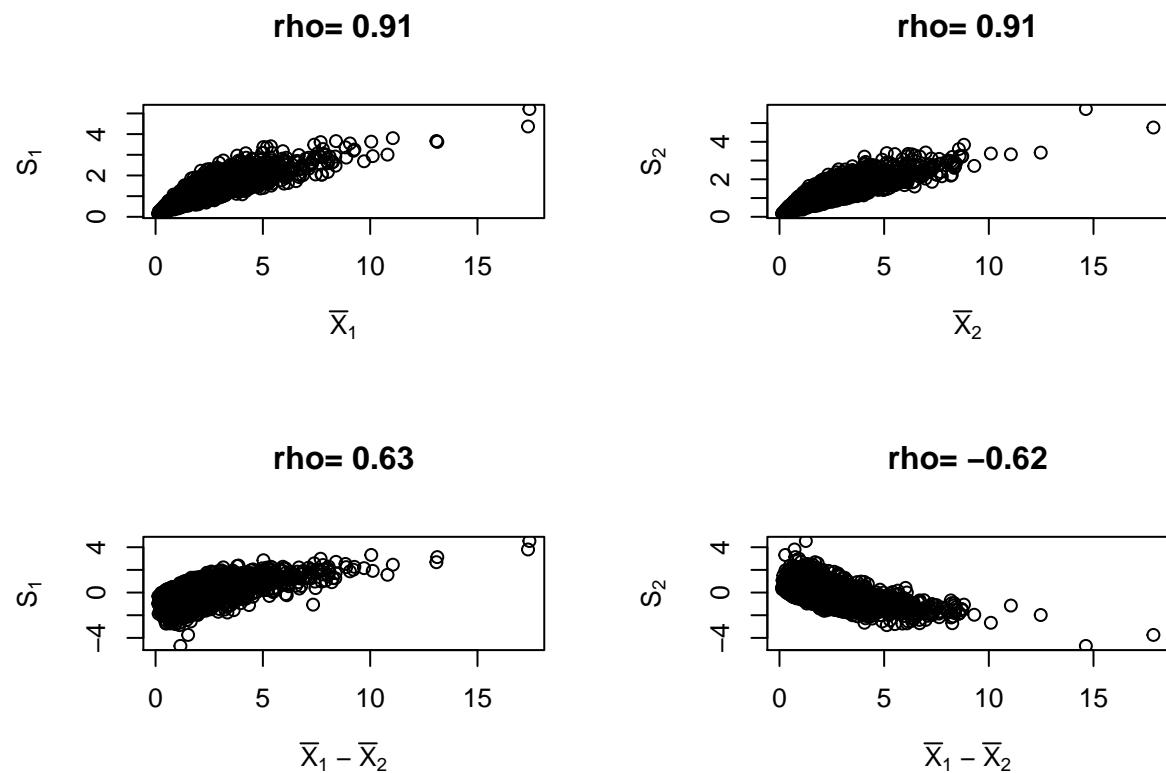

Figure 2.  $S_j$  ( $j=1,2$ ) as a function  $\bar{X}_j$  (top plots) or  $\bar{X}_1 - \bar{X}_2$  (bottom plots), when samples are extracted from right skewed distributions ( $\gamma_1 = 6.32$ ; top plots)

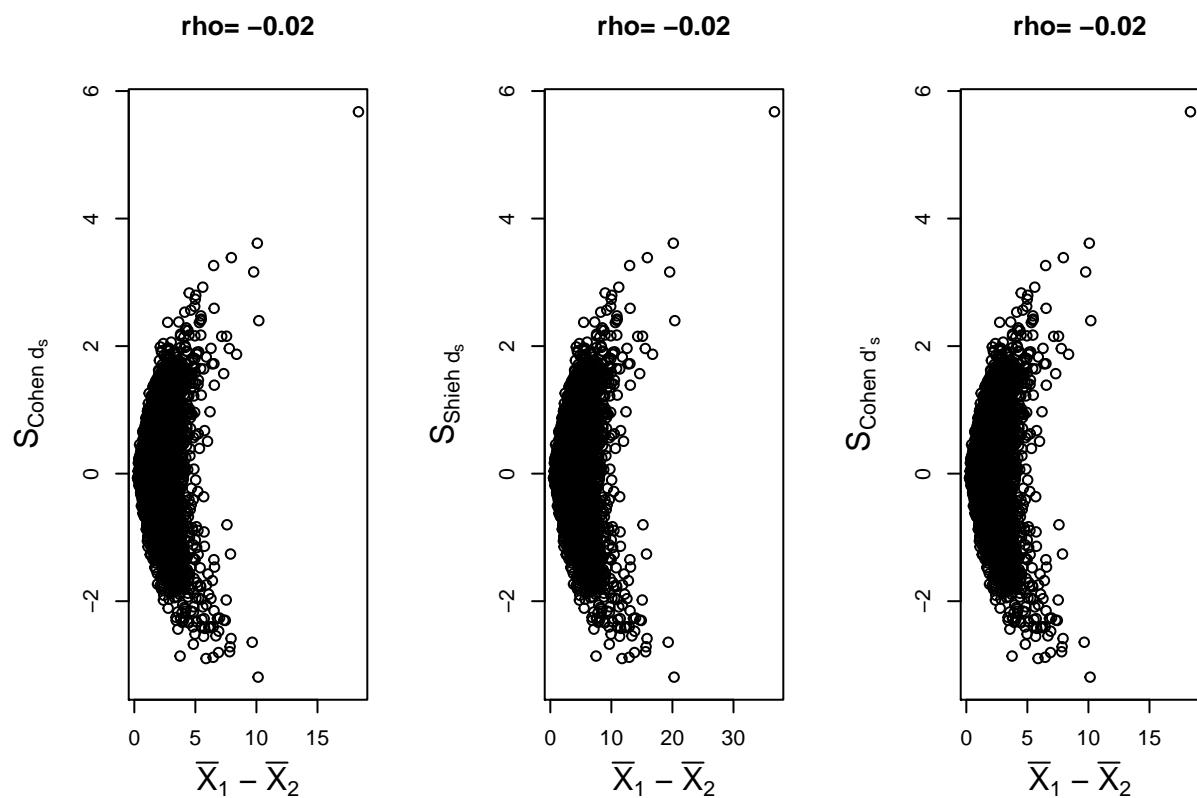

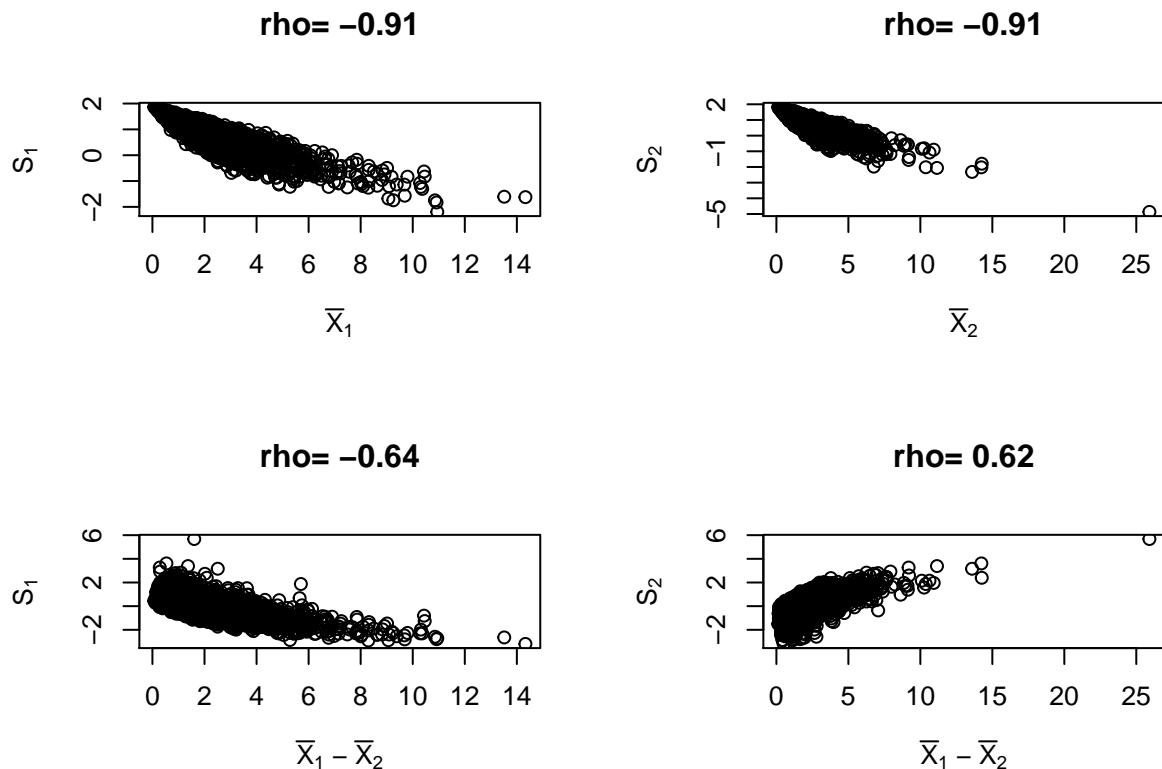

Figure 3.  $S_{Glass's} d_s$ ,  $S_{Shieh's} d_s$  and  $S_{Cohen's} d'_s$  as a function of the means difference ( $\bar{X}_1 - \bar{X}_2$ ), when samples are extracted from right skewed distributions ( $\gamma_1 = 6.32$ )

*Figure 4.*  $S_j$  ( $j=1,2$ ) as a function  $\bar{X}_j$  (top plots) or  $\bar{X}_1 - \bar{X}_2$  (bottom plots), when samples are extracted from left skewed distributions ( $\gamma_1 = -6.32$ ; top plots)

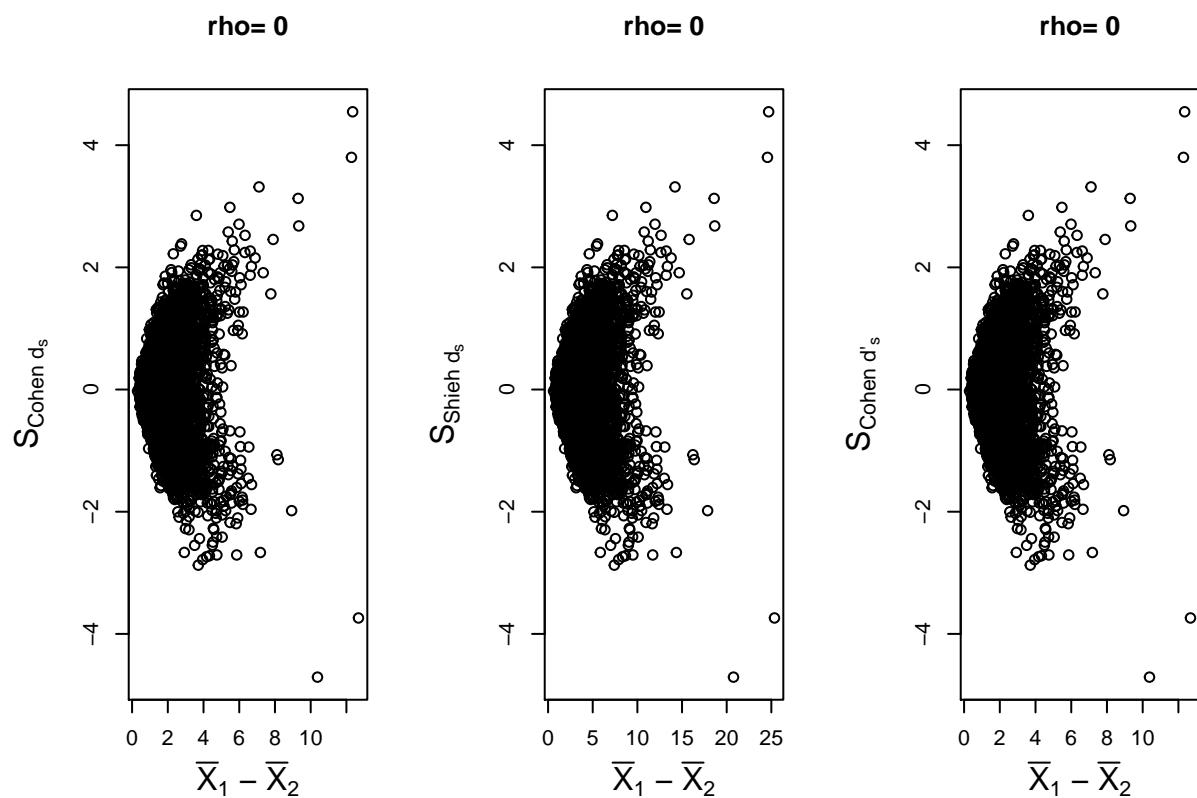

Figure 5.  $S_{Glass's} d_s$ ,  $S_{Shieh's} d_s$  and  $S_{Cohen's} d_s$  as a function of the means difference ( $\bar{X}_1 - \bar{X}_2$ ), when samples are extracted from left skewed distributions ( $\gamma_1 = -6.32$ )

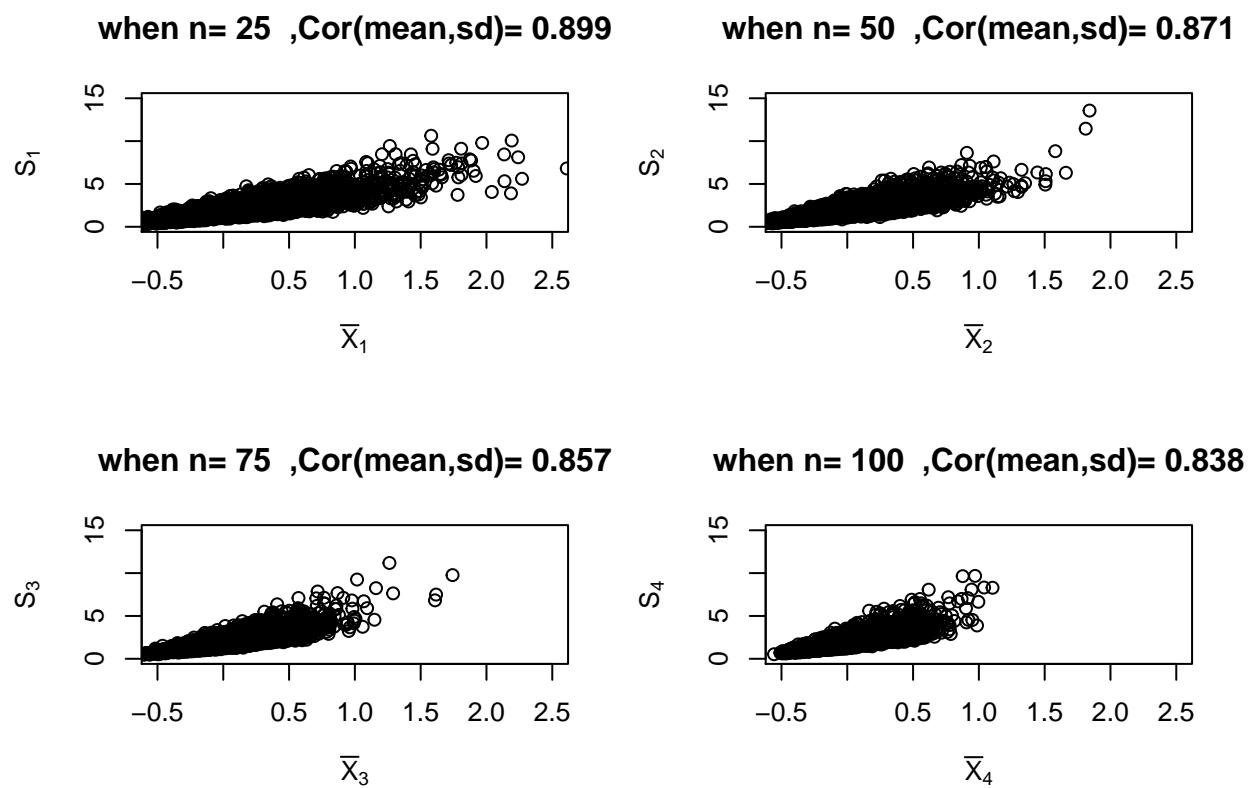

Figure 6. correlation between  $S_j$  and  $\bar{X}_j$  when  $n = 25, 50, 75$  or  $100$  and samples are extracted from right skewed distributions ( $\gamma_1 = 6.32$ )

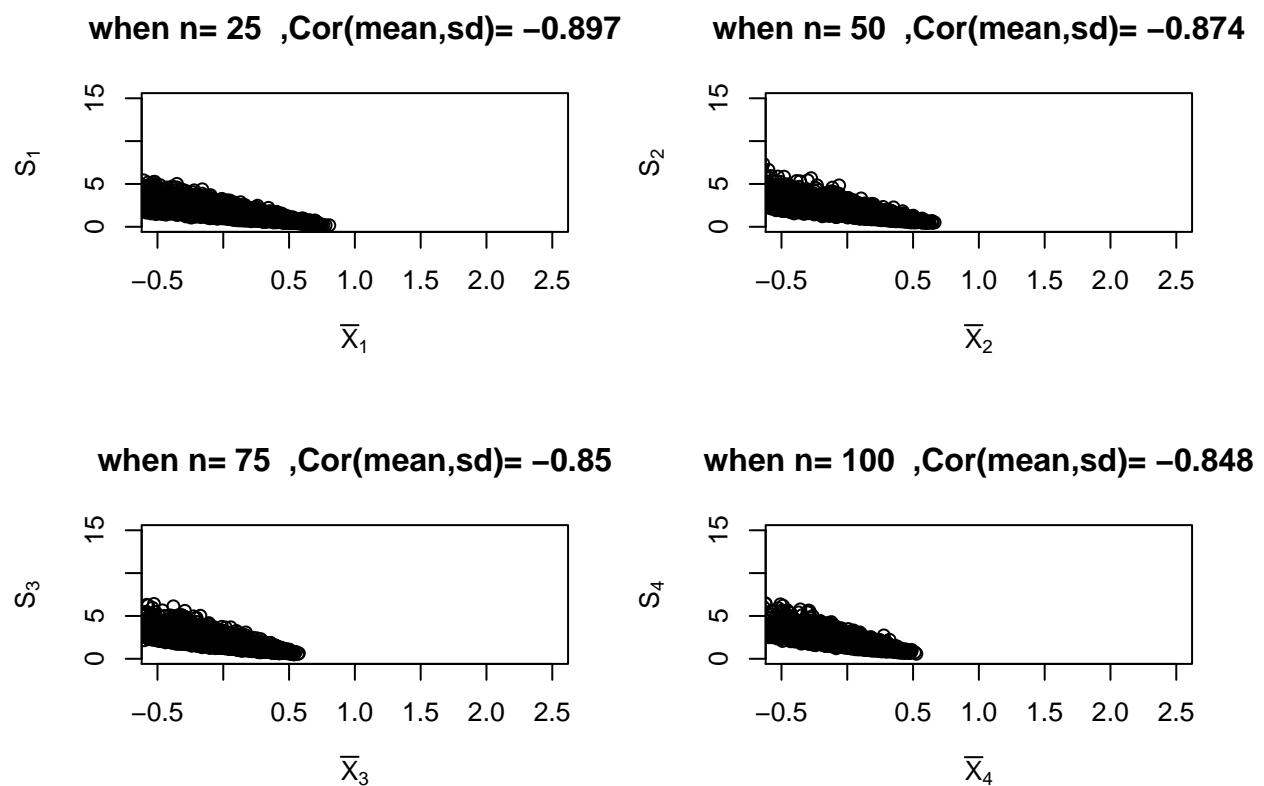

Figure 7. correlation between  $S_j$  and  $\bar{X}_j$  when  $n = 25, 50, 75$  or  $100$  and samples are extracted from right left distributions ( $\gamma_1 = -6.32$ )

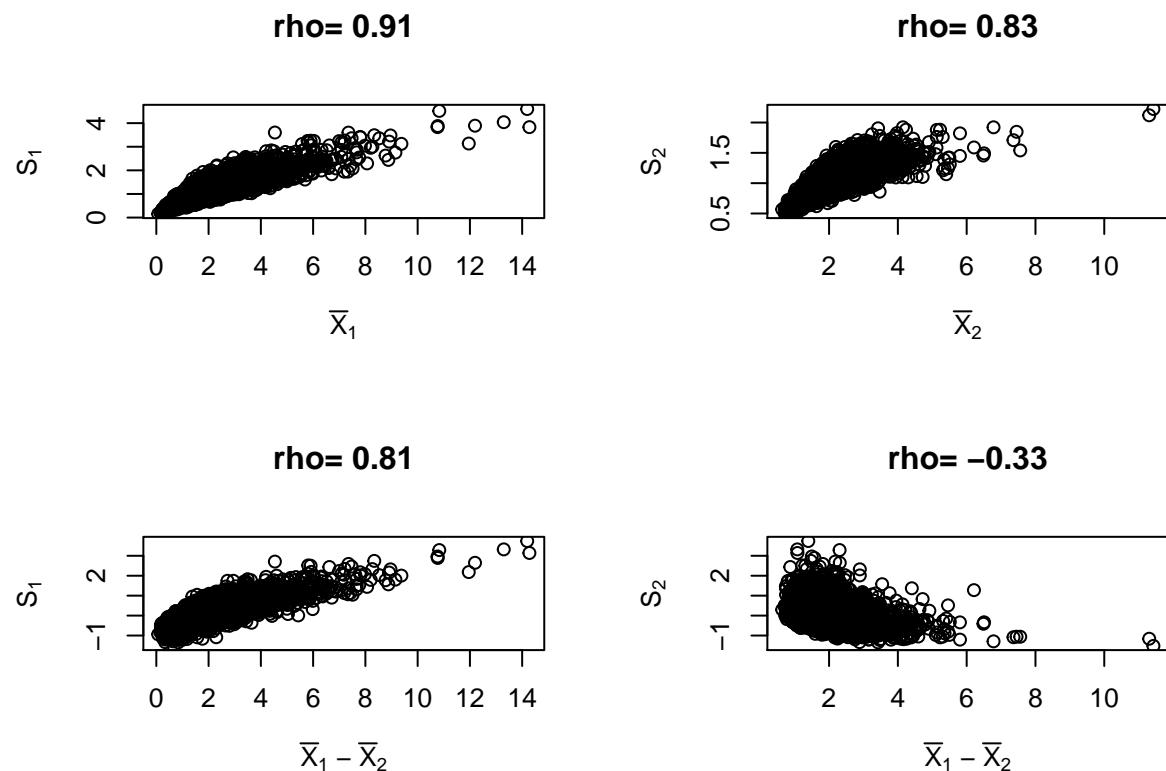

Figure 8.  $S_j$  ( $j=1,2$ ) as a function  $\bar{X}_j$  (top plots) or  $\bar{X}_1 - \bar{X}_2$  (bottom plots), when samples are extracted from right skewed distributions ( $\gamma_1 = 6.32$ ; top plots), with  $n1=20$  and  $n2=100$

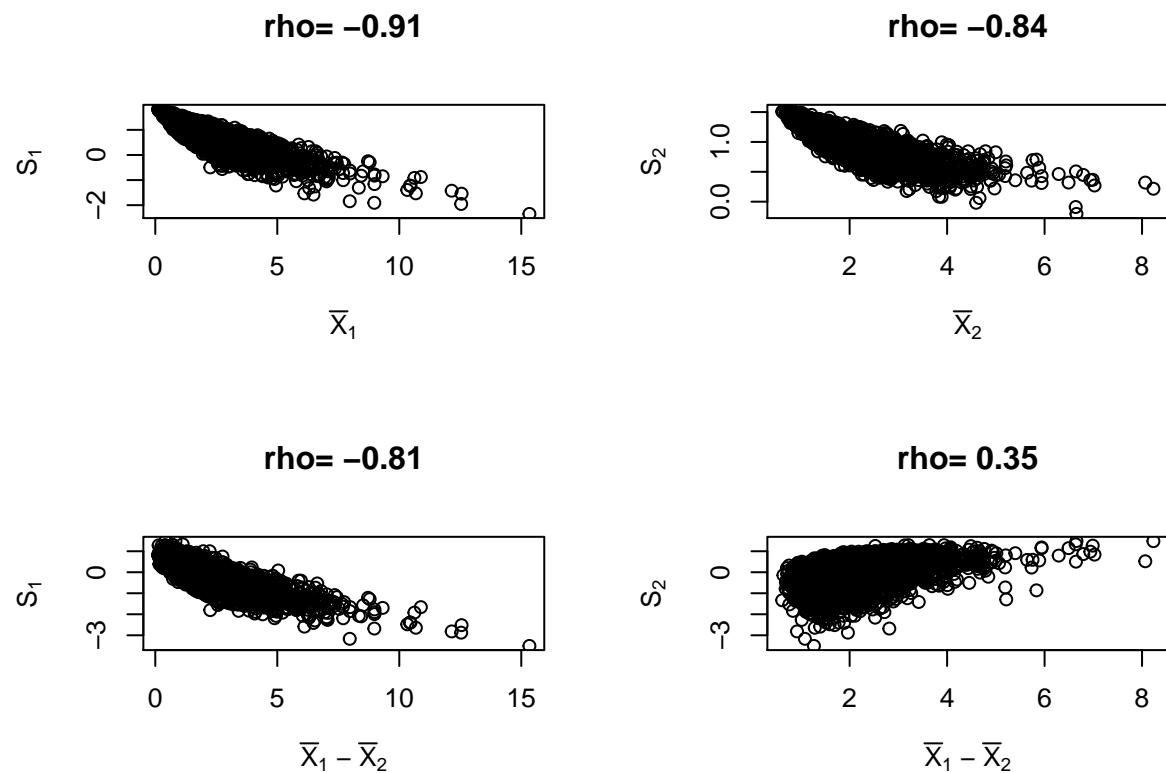

Figure 9.  $S_j$  ( $j=1,2$ ) as a function  $\bar{X}_j$  (top plots) or  $\bar{X}_1 - \bar{X}_2$  (bottom plots), when samples are extracted from left skewed distributions ( $\gamma_1 = -6.32$ ; top plots), with  $n1=20$  and  $n2=100$

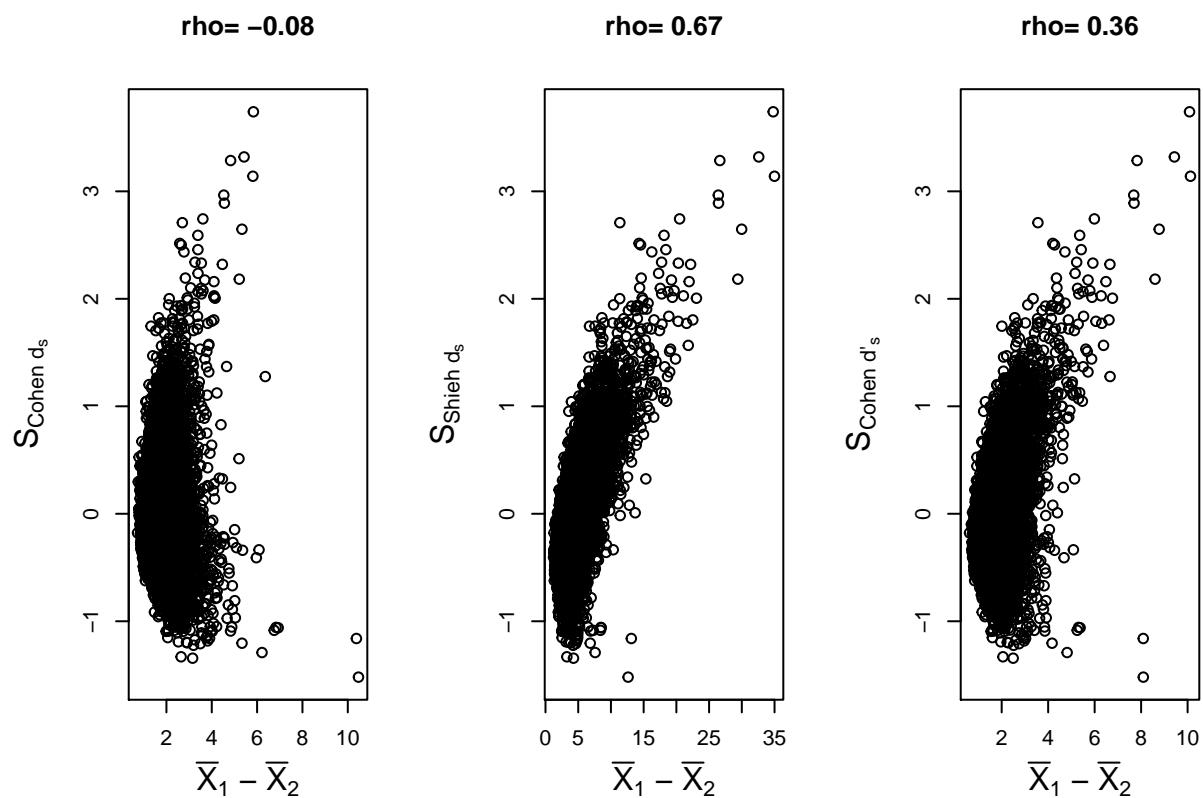

Figure 10.  $S_{Glass's\,d_s}$ ,  $S_{Shieh's\,d_s}$  and  $S_{Cohen's\,d'_s}$  as a function of the means difference ( $\bar{X}_1 - \bar{X}_2$ ), when samples are extracted from right skewed distributions ( $\gamma_1 = 6.32$ )

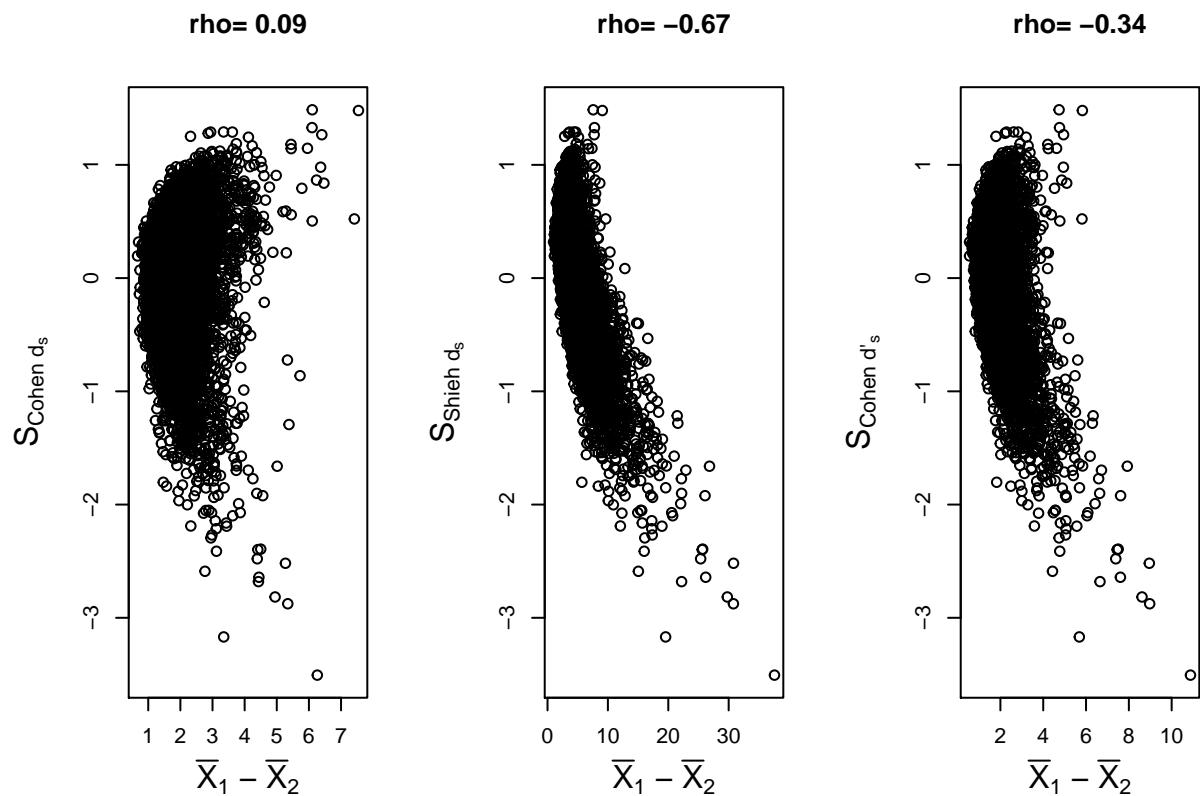

Figure 11.  $S_{Glass's} d_s$ ,  $S_{Shieh's} d_s$  and  $S_{Cohen's} d'_s$  as a function of the means difference ( $\bar{X}_1 - \bar{X}_2$ ), when samples are extracted from left skewed distributions ( $\gamma_1 = -6.32$ )

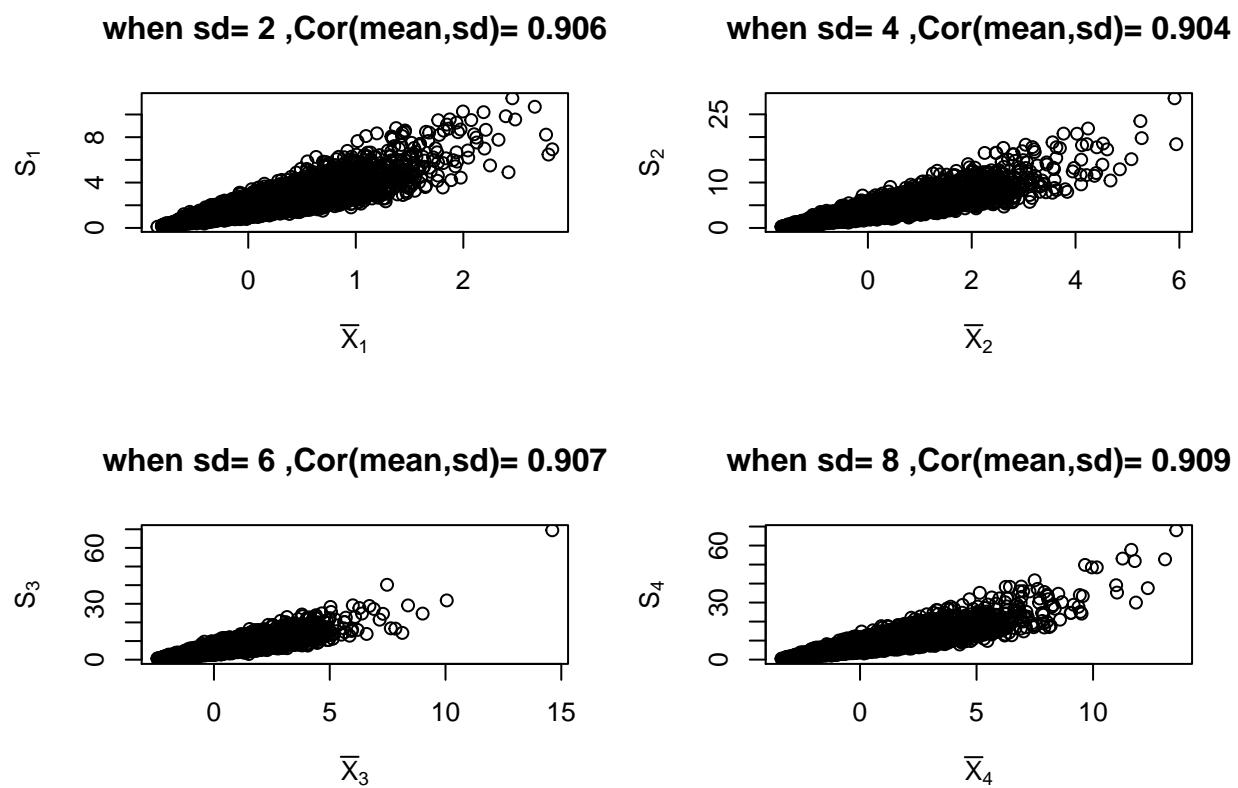

Figure 12. correlation between  $S_j$  and  $\bar{X}_j$  when  $n = 25, 50, 75$  or  $100$  and samples are extracted from right skewed distributions ( $\gamma_1 = 6.32$ )

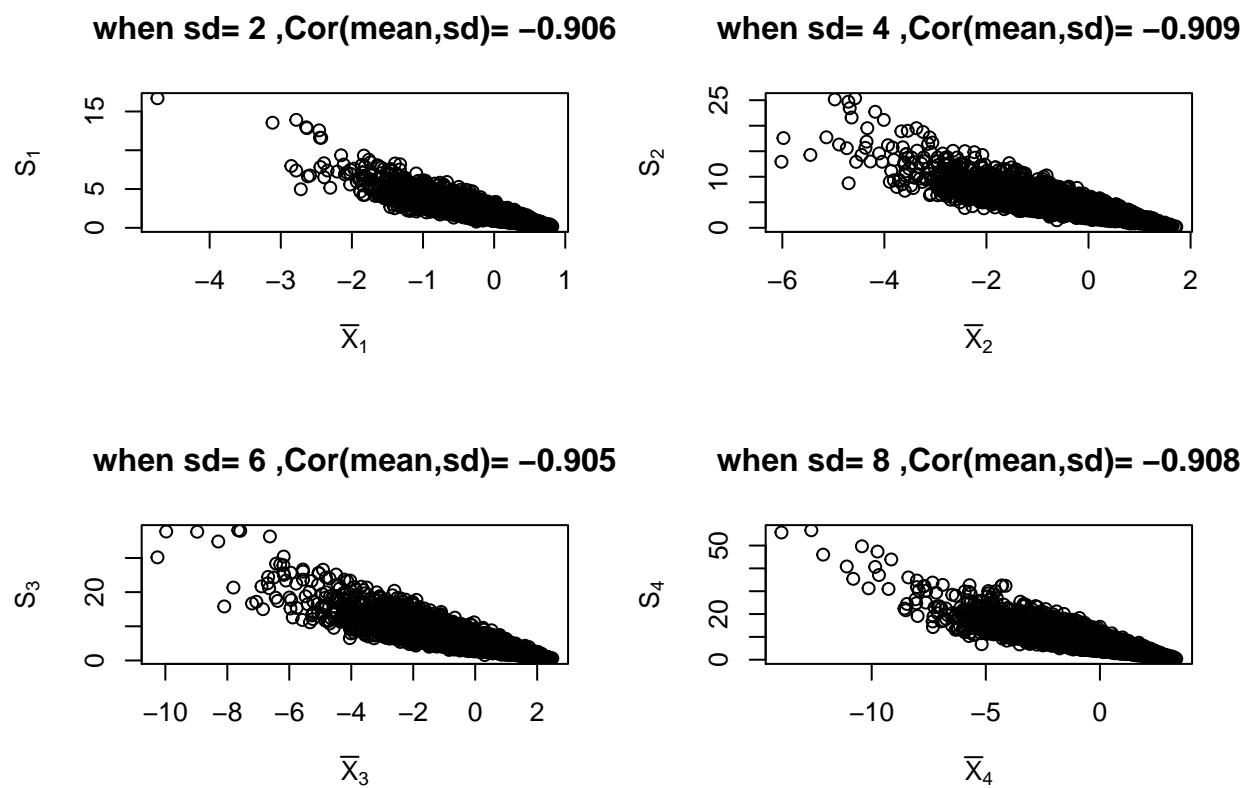

Figure 13. correlation between  $S_j$  and  $\bar{X}_j$  when  $n = 25, 50, 75$  or  $100$  and samples are extracted from left skewed distributions ( $\gamma_1 = -6.32$ )

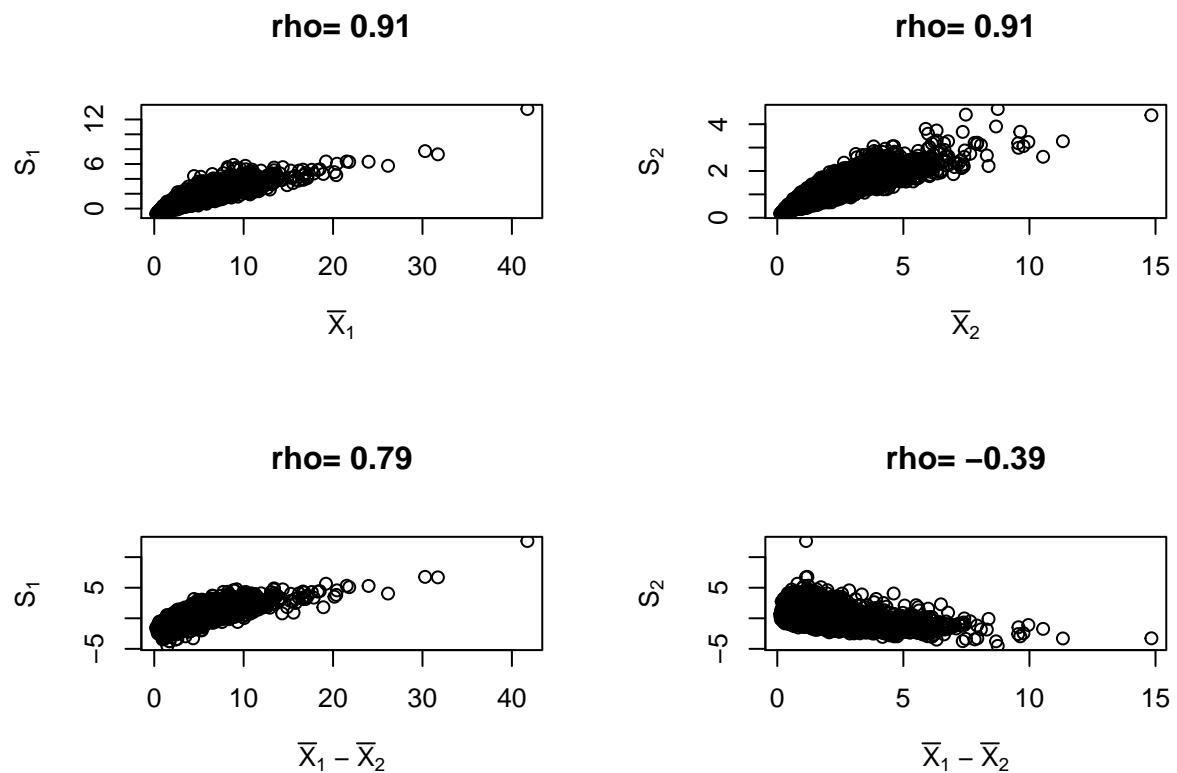

Figure 14.  $S_j$  ( $j=1,2$ ) as a function  $\bar{X}_j$  (top plots) or  $\bar{X}_1 - \bar{X}_2$  (bottom plots), when samples are extracted from right skewed distributions ( $\gamma_1 = 6.32$ ; top plots), with  $n1=20$  and  $n2=100$

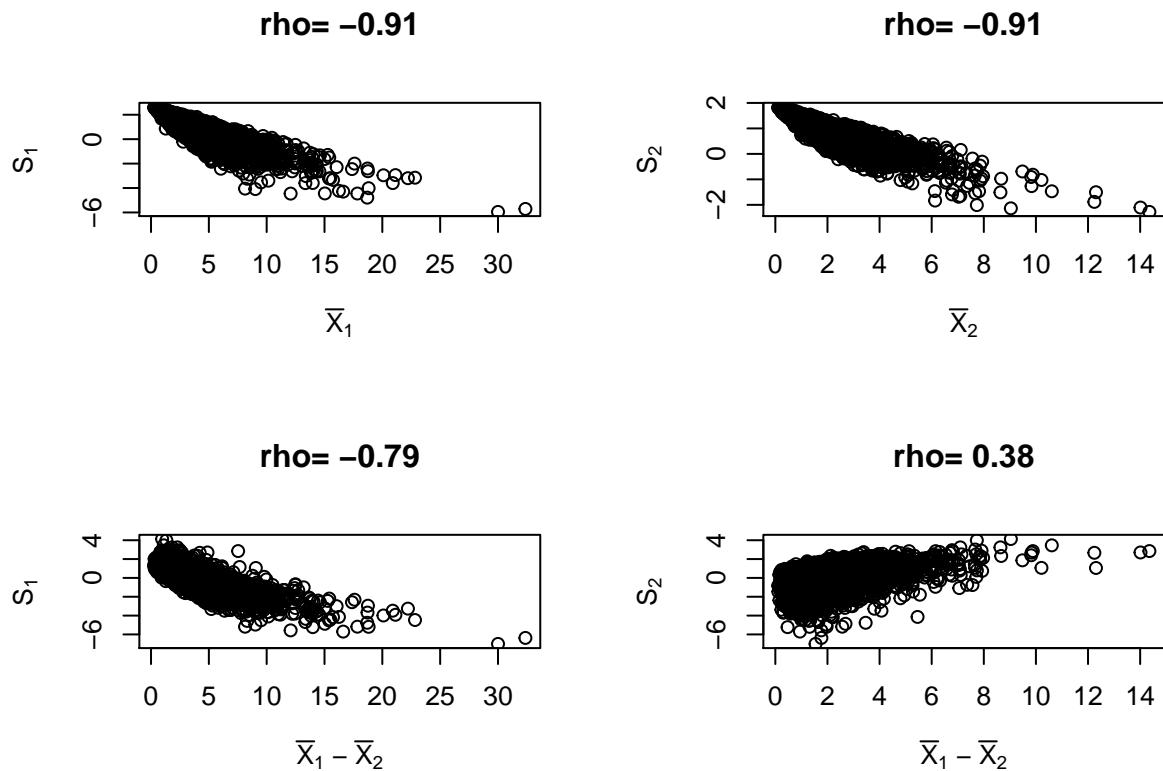

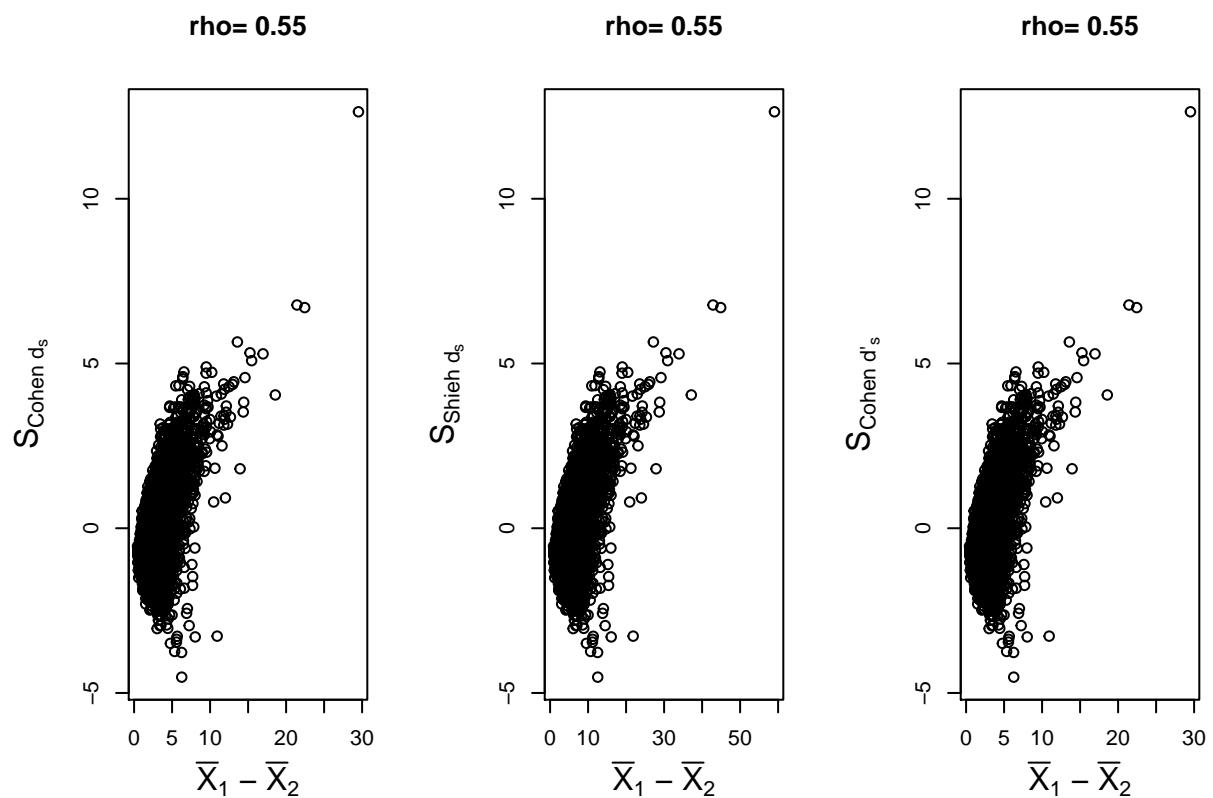

Figure 15.  $S_j$  ( $j=1,2$ ) as a function  $\bar{X}_j$  (top plots) or  $\bar{X}_1 - \bar{X}_2$  (bottom plots), when samples are extracted from left skewed distributions ( $\gamma_1 = -6.32$ ; top plots), with  $n1=20$  and  $n2=100$

*Figure 16.*  $S_{Glass's} d_s$ ,  $S_{Shieh's} d_s$  and  $S_{Cohen's} d'_s$  as a function of the means difference ( $\bar{X}_1 - \bar{X}_2$ ), when samples are extracted from right skewed distributions ( $\gamma_1 = 6.32$ )

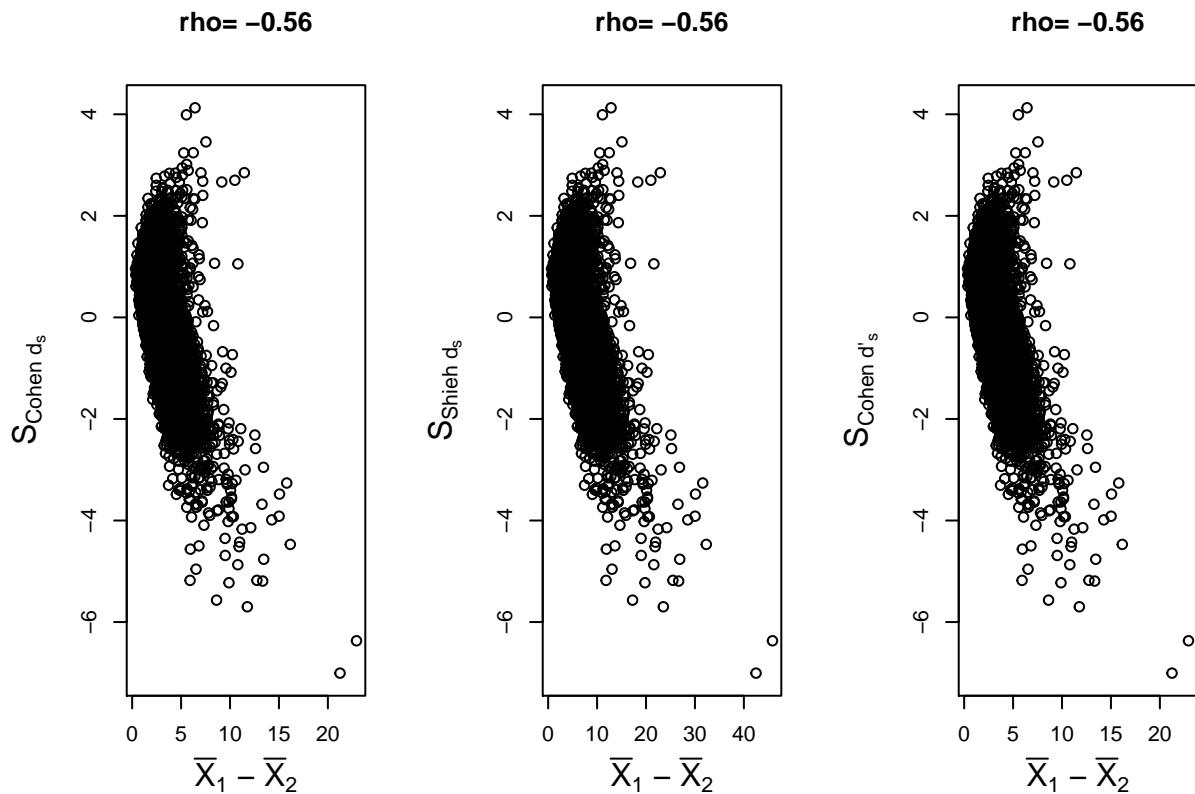

Figure 17.  $S_{Glass's\,d_s}$ ,  $S_{Shieh's\,d_s}$  and  $S_{Cohen's\,d'_s}$  as a function of the means difference ( $\bar{X}_1 - \bar{X}_2$ ), when samples are extracted from left skewed distributions ( $\gamma_1 = -6.32$ )
